marelac: Tools for Aquatic Sciences

Karline Soetaert NIOZ-Yerseke The Netherlands Thomas Petzoldt Technische Universität Dresden Germany Filip Meysman NIOZ-Yerseke The Netherlands

Abstract

R package **marelac** (Soetaert, Petzoldt, and Meysman 2010) contains chemical and physical constants and functions, datasets, routines for unit conversion, and other utilities useful for MArine, Riverine, Estuarine, LAcustrine and Coastal sciences.

Keywords: marine, riverine, estuarine, lacustrine, coastal science, utilities, constants, R.

1. Introduction

R package **marelac** has been designed as a tool for use by scientists working in the MArine, Riverine, Estuarine, LAcustrine and Coastal sciences.

It contains:

- chemical and physical constants, datasets, e.g. atomic weights, gas constants, the earths bathymetry.
- conversion factors, e.g. gram to mol to liter conversions; conversions between different barometric units, temperature units, salinity units.
- physical functions, e.g. to estimate concentrations of conservative substances as a function of salinity, gas transfer coefficients, diffusion coefficients, estimating the Coriolis force, gravity ...
- the thermophysical properties of the seawater, as from the UNESCO polynomial (Fofonoff and Millard 1983) or as from the more recent derivation based on a Gibbs function (Feistel 2008; McDougall, Feistel, Millero, Jackett, Wright, King, Marion, Chen, and Spitzer 2009a).

Package **marelac** does *not* contain chemical functions dealing with the aquatic carbonate system (acidification, pH). These function can be found in two other R packages, i.e. **seacarb** (Lavigne and Gattuso 2010) and **AquaEnv** (Hofmann, Soetaert, Middelburg, and Meysman 2010).

2. Constants and datasets

2.1. Physical constants

Dataset Constants contains commonly used physical and chemical constants, as in Mohr and Taylor (2005):

```
> data.frame(cbind(acronym = names(Constants),
               matrix(ncol = 3, byrow = TRUE, data = unlist(Constants),
               dimnames=list(NULL, c("value", "units", "description"))))
+

```

2.2. Ocean characteristics

Dataset Oceans contains surfaces and volumes of the world oceans as in Sarmiento and Gruber (2006):

```
> data.frame(cbind(acronym = names(Oceans),
               matrix(ncol = 3, byrow = TRUE, data = unlist(Oceans),
+
               dimnames = list(NULL, c("value", "units", "description")))))
                                                            description
     acronym
                value units
1

                         m2
```

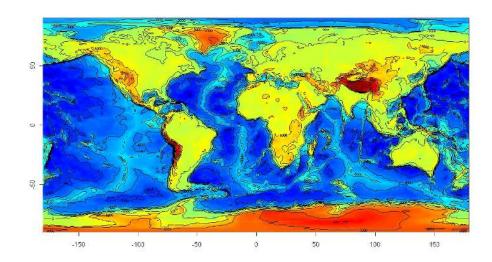

Figure 1: Image plot of ocean bathymetry - see text for R-code

```
10 AreaArct 9.6e+12 m2 area of the Arctic ocean
11 AreaEncl 4.5e+12 m2 area of enclosed seas (e.g. Mediterranean)
12 Depth 3690 m mean depth of the oceans
13 RiverFlow 3.7e+13 m3/yr Total river flow
```

2.3. World bathymetric data

Data set Bathymetry from the marelac package can be used to generate the bathymetry (and hypsometry) of the world oceans (and land) (Fig.1):

2.4. Surface of 1 dg by 1 dg grid cells of the earth

Function earth_surf estimates the surface (m²) of the bathymetric grid cells of 1dg by 1dg, based on their latitude.

As an example, we use it to estimate the surface of the earth; the true surface is 510072000 km²:

```
> SURF <- outer(X = Bathymetry$x,
+ Y = Bathymetry$y,
+ FUN <- function(X, Y) earth_surf(Y, X))
> sum(SURF)
```

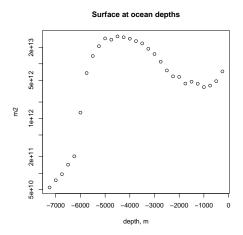

Figure 2: Earth surface at certain ocean depths - see text for R-code

[1] 5.100718e+14

Similarly, we can estimate the surface and volume of the oceans; it should be $3.58e^{14}$ and $1.34e^{+18}$ respectively.

```
> sum(SURF*(Bathymetry$z < 0))
[1] 3.618831e+14
> - sum(SURF*Bathymetry$z*(Bathymetry$z < 0))
[1] 1.336255e+18</pre>
```

Combined with the dataset Bathymetry, function earth_surf allows to estimate the total earth surface at certain water depths (Fig.2):

```
> SurfDepth <- vector()
> dseq <- seq(-7500, -250, by = 250)
> for (i in 2:length(dseq)) {
+    ii <- which (Bathymetry$z > dseq[i-1] & Bathymetry$z <= dseq[i])
+    SurfDepth[i-1] <- sum(SURF[ii])
+ }
> plot(dseq[-1], SurfDepth, xlab="depth, m", log = "y",
+    ylab = "m2", main = "Surface at ocean depths")
```

2.5. AtomicWeight

Dataset AtomicWeight holds the atomic weight of most chemical elements according to the IUPAC table (Wieser 2006). The data set contains NA for elements which have no stable

isotopes (except U, Th, Pa). The data set can be called in two versions. AtomicWeight shows the full table and atomicweight can be used for symbolic computations with the elements (see also molweight).

2.6. Atmospheric composition

The atmospheric composition, given in units of the moles of each gas to the total of moles of gas in dry air is in function atmComp:

```
He Ne N2 O2 Ar Kr
5.2400e-06 1.8180e-05 7.8084e-01 2.0946e-01 9.3400e-03 1.1400e-06

O3
1.0000e-08
> sum(atmComp()) #!
```

3. Physical functions

3.1. Coriolis

Function coriolis estimates the Coriolis factor, f, units sec^{-1} according to the formula: $f = 2 * \omega * \sin(lat)$, where $\omega = 7.292e^{-5}$ radians sec^{-1} .

The following R-script plots the coriolis factor as a function of latitude (Fig.3):

```
> plot(-90:90, coriolis(-90:90), xlab = "latitude, dg North",
+ ylab = "/s" , main = "Coriolis factor", type = "l", lwd = 2)
```

3.2. Molecular diffusion coefficients

In function diffcoeff the molecular and ionic diffusion coefficients (m²s⁻¹), for several species at given salinity (S) temperature (t) and pressure (P) is estimated. The implementation is based on Chapter 4 in (Boudreau 1997).

```
> diffcoeff(S = 15, t = 15)*24*3600*1e4 # cm2/day
```

```

Molecular/ionic diffusion

Figure 4: Molecular diffusion coefficients as a function of temperature

temperature

4. Dissolved gasses

4.1. Saturated oxygen concentrations

gas_02sat estimates the saturated concentration of oxygen in mgL⁻¹. Method APHA (Greenberg 1992) is the standard formula in Limnology, the method after Weiss (1970) the traditional formula used in marine sciences.

```
> gas_02sat(t = 20)
[1] 7.374404
> t <- seq(0, 30, 0.1)</pre>
```

Conversion to $mmol^m-3$ can be done as follows:

shear viscosity of water

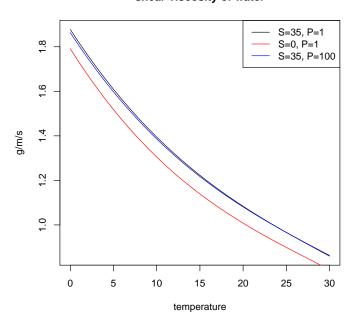

Figure 5: Shear viscosity of water as a function of temperature

The effect of salinity on saturated concentration is in (Fig.6).

```
> plot(t, gas_02sat(t = t), type = "1", ylim = c(0, 15), lwd = 2,
+ main = "0xygen saturation", ylab = "mg/l", xlab = "temperature")
> lines(t, gas_02sat(S = 0, t = t, method = "Weiss"), col = "green",
+ lwd = 2, lty = "dashed")
> lines(t, gas_02sat(S = 35, t = t, method = "Weiss"), col = "red", lwd = 2)
> legend("topright", c("S=35", "S=0"), col = c("red", "green"),
+ lty = c(1, 2), lwd = 2)
```

4.2. Solubilities and saturated concentrations

More solubilities and saturated concentrations (in mmolm⁻³) are in functions gas_solubility and gas_satconc.

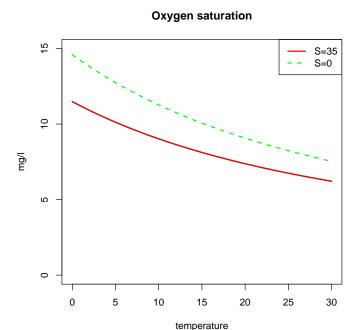

Figure 6: Oxygen saturated concentration as a function of temperature, and for different salinities

```
> Temp <- seq(from = 0, to = 30, by = 0.1)
> Sal <- seq(from = 0, to = 35, by = 0.1)
```

We plot the saturated concentrations for a selection of species as a function of temperature and salinity (Fig.7):

```
> #
     <-par(mfrow = c(2, 2))
> mf
> gs <-gas_solubility(t = Temp)</pre>
            <- c("CC14", "CO2", "N20", "Rn", "CC12F2")
> species
> matplot(Temp, gs[, species], type = "l", lty = 1, lwd = 2, xlab = "temperature",
       ylab = "mmol/m3", main = "solubility (S=35)")
> legend("topright", col = 1:5, lwd = 2, legend = species)
> #
> species2 <- c("Kr", "CH4", "Ar", "O2", "N2", "Ne")
> matplot(Temp, gs[, species2], type = "l", lty = 1, lwd = 2, xlab = "temperature",
       ylab = "mmol/m3", main = "solubility (S=35)")
> legend("topright", col = 1:6, lwd = 2, legend = species2)
> #
> species <- c("N2", "CO2", "O2", "CH4", "N2O")
> gsat <-gas_satconc(t = Temp, species = species)</pre>
```

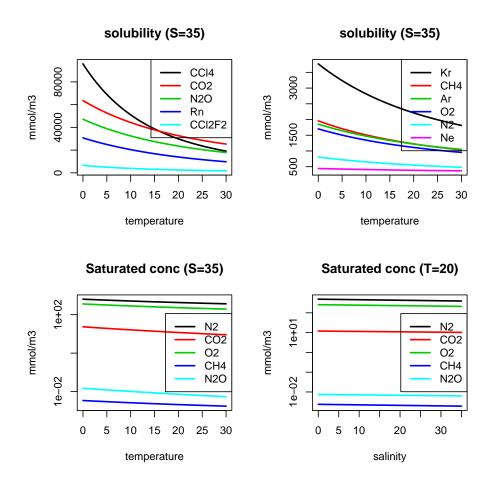

Figure 7: Saturated concentrations and solubility as a function of temperature and salinity, and for different species

4.3. Partial pressure of water vapor

Function vapor estimates the partial pessure of water vapor, divided by the atmospheric pressure (Fig.8).

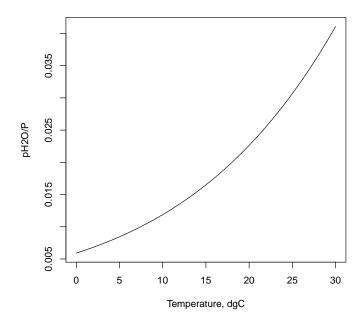

Figure 8: Partial pressure of water in saturated air as a function of temperature

```
> plot(0:30, vapor(t = 0:30), xlab = "Temperature, dgC", ylab = "pH20/P", type = "l")
```

4.4. Schmidt number and gas transfer velocity

The Schmidt number of a gas (gas_schmidt) is an essential quantity in the gas transfer velocity calculation (gas_transfer). The latter also depends on wind velocity, as measured 10 metres above sea level (u_{10}) (Fig.9).

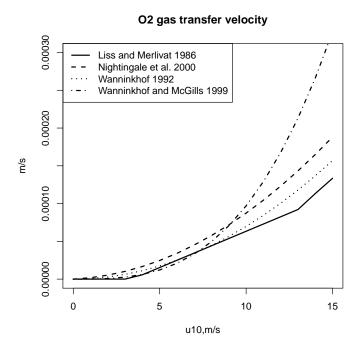

Figure 9: Oxygen gas transfer velocity for seawater, as a function of wind speed

```
> lines(useq, gas_transfer(u10 = useq, species = "02", method = "Wanninkhof2"),
+ lwd = 2, lty = 4)
> legend("topleft", lty = 1:4, lwd = 2, legend = c("Liss and Merlivat 1986",
+ "Nightingale et al. 2000", "Wanninkhof 1992", "Wanninkhof and McGills 1999"))
```

5. Seawater properties

5.1. Concentration of conservative species in seawater

Borate, calcite, sulphate and fluoride concentrations can be estimated as a function of the seawater salinity:

```
Borate
              Calcite
                       Sulphate
                                 Fluoride
    0.00000
                          0.000
                                 0.00000
                0.000
  59.42857
             1468.571
                       4033.633
                                 9.760629
                       8067.267 19.521257
3 118.85714
             2937.143

             4405.714 12100.900 29.281886
             5874.286 16134.534 39.042515
5 237.71429
6 297.14286
             7342.857 20168.167 48.803144
7 356.57143 8811.429 24201.801 58.563772
8 416.00000 10280.000 28235.434 68.324401
```

> sw_conserv(S = seq(0, 35, by = 5))

5.2. Two salinity scales

Millero, Feistel, Wright, and McDougall (2008) and McDougall, Jackett, and Millero (2009b) provide a function to derive absolute salinity (expressed in g~kg⁻¹) from measures of practical salinity. Absolute salinity is to be used as the concentration variable entering the thermodynamic functions of seawater (see next section).

The conversion between salinity scales is done with functions:

- convert_AStoPS from absolute to practical salinity and
- convert_PStoAS from practical to absolute salinity

For example:

```
> convert_AStoPS(S = 35)
[1] 34.83573
> convert_PStoAS(S = 35)
[1] 35.16504
```

These functions have as extra arguments the gauge pressure (p), latitude (lat), longitude (lon), and -optional- the dissolved Si concentration (DSi) and the ocean (Ocean).

When one of these arguments are provided, they also correct for inconsistencies due to local composition anomalies.

When DSi is not given, the correction makes use of a conversion table that estimates the salinity variations as a function of present-day local seawater composition. The conversion in R uses the FORTRAN code developed by D. Jackett (http://www.marine.csiro.au/~jackett/TEOS-10/).

The correction factors are in a data set called sw_sfac, a list with the properties used in the conversion functions.

Below we first convert from practical to absolute salinity, for different longitudes, and then plot the correction factors as a function of latitude and longitude and at the seawater surface, i.e. for p=0 (Fig.10).¹.

```
> convert_PStoAS(S = 35, lat = -10, lon = 0)
[1] 35.16525
> convert_PStoAS(S = 35, lat = 0, lon = 0)
[1] 35.16558
```

¹Before plotting, the negative numbers in the salinity anomaly table sw_sfac are converted to NA (not available). In the data set, numbers not available are denoted with -99.

Figure 10: Salinity anomaly to convert from practical to absolute salinity and vice versa

dg

Finally, the correction factors are plotted versus depth, at four latitudinal cross-sections (Fig.11):

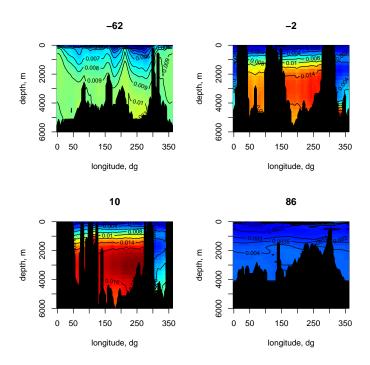

Figure 11: Salinity anomaly to convert from practical to absolute salinity and vice versa for several latitudinal cross-sections (negative = S hemisphere)

5.3. Thermophysical seawater properties

Package **marelac** also implements several thermodynamic properties of seawater. Either one can choose the formulation based on the UNESCO polynomial (Fofonoff and Millard 1983), which has served the oceanographic community for decades, or the more recent derivation as in Feistel (2008). In the latter case the estimates are based on three individual thermodynamic potentials for fluid water, for ice and for the saline contribution of seawater (the Helmholtz function for pure water, an equation of state for salt-free ice, in the form of a Gibbs potential function, and the saline part of the Gibbs potential).

Note that the formulations from Feistel (2008) use the absolute salinity scale (Millero et~al.

2008), while the UNESCO polynomial uses practical salinity.

```
> sw_cp(S = 40,t = 1:20)

[1] 3958.545 3959.028 3959.576 3960.180 3960.831 3961.523 3962.247
[8] 3962.997 3963.768 3964.553 3965.348 3966.148 3966.949 3967.747
[15] 3968.540 3969.324 3970.098 3970.859 3971.605 3972.336

> sw_cp(S = 40,t = 1:20, method = "UNESCO")

[1] 3956.080 3955.898 3955.883 3956.021 3956.296 3956.697 3957.209
```

[8] 3957.819 3958.516 3959.288 3960.124 3961.013 3961.945 3962.911

[15] 3963.900 3964.906 3965.918 3966.931 3967.936 3968.927

The precision of the calculations can be assessed by comparing them to some test values:

> sw_entropy(S, t, p) -352.81879771528

[1] -9.916204e-08

Below we plot all implemented thermophysical properties as a function of salinity and temperature (Fig.12, 13). We first define a function that makes the plots:

```
> plotST <- function(fun, title)</pre>
+ {
   Sal \leftarrow seq(0, 40, by = 0.5)
   Temp \leftarrow seq(-5, 40, by = 0.5)
  Val \leftarrow outer(X = Sal, Y = Temp, FUN = function(X, Y) fun(S = X, t = Y))
   contour(Sal, Temp, Val, xlab = "Salinity", ylab = "temperature",
           main = title, nlevel = 20)
+ }
> par (mfrow = c(3, 2))
> par(mar = c(4, 4, 3, 2))
> plotST(sw_gibbs, "Gibbs function")
> plotST(sw_cp, "Heat capacity")
> plotST(sw_entropy, "Entropy")
> plotST(sw_enthalpy, "Enthalpy")
> plotST(sw_dens, "Density")
> plotST(sw_svel, "Sound velocity")
> par (mfrow = c(3, 2))
> par(mar = c(4, 4, 3, 2))
> plotST(sw_kappa, "Isentropic compressibility")
> plotST(sw_kappa_t, "Isothermal compressibility")
> plotST(sw_alpha, "Thermal expansion coefficient")
> plotST(sw_beta, "Haline contraction coefficient")
> plotST(sw_adtgrad, "Adiabatic temperature gradient")
> par (mfrow = c(1, 1))
```

The difference between the two formulations, based on the UNESCO polynomial or the Gibss function is also instructive (Fig.14):

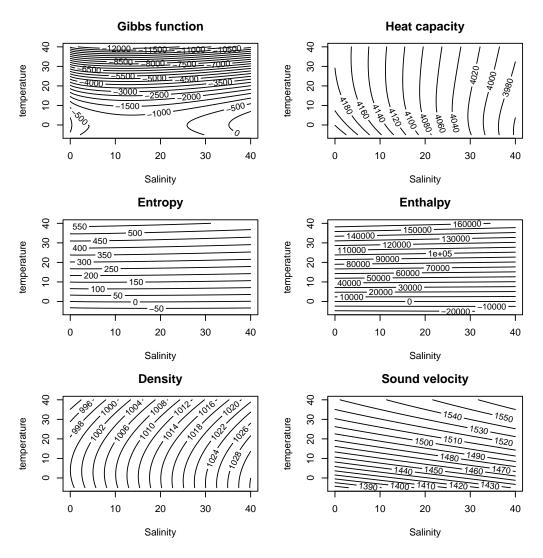

Figure 12: Seawater properties as a function of salinity and temperature - see text for R-code

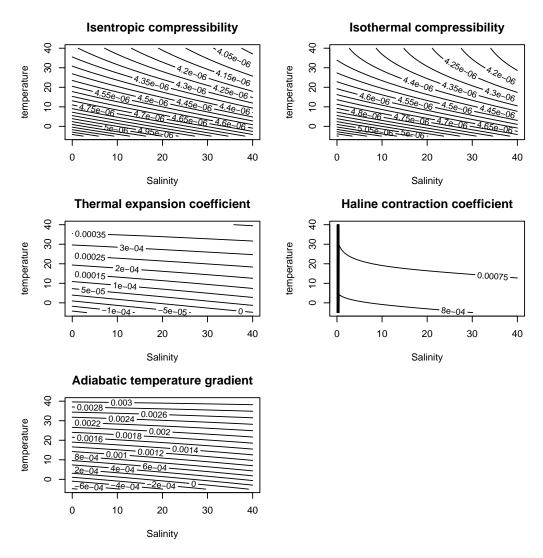

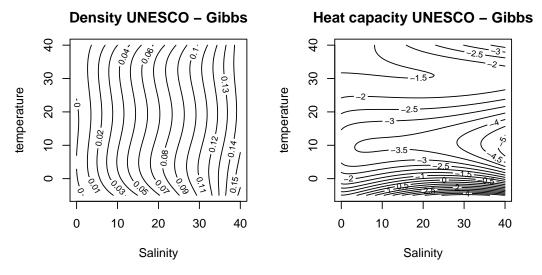

Figure 13: Seawater properties as a function of salinity and temperature - continued - see text for $\mathsf{R}\text{-}\mathsf{code}$

Sound velocity UNESCO - Gibbs

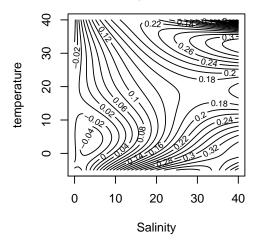

Figure 14: Difference between two methods of calculating some seawater properties as a function of salinity and temperature - see text for R-code

```
> par (mfrow = c(2, 2))
> par(mar = c(4, 4, 3, 2))
> plotST(function(S, t) sw_dens(S, t, method = "UNESCO") - sw_dens(S, t),
+ "Density UNESCO - Gibbs")
> plotST(function(S, t) sw_cp(S, t, method = "UNESCO") - sw_cp(S, t),
+ "Heat capacity UNESCO - Gibbs")
> plotST(function(S, t) sw_svel(S, t, method = "UNESCO") - sw_svel(S, t),
+ "Sound velocity UNESCO - Gibbs")
> par (mfrow = c(1, 1))
```

6. Conversions

Finally, several functions are included to convert between units of certain properties.

6.1. Gram, mol, liter conversions

> molvol(species = "ideal")

marelac function molweight converts from gram to moles and vice versa. The function is based on a lexical parser and the IUPAC table of atomic weights, so it should be applicable to arbitrary chemical formulae:

```
> 1/molweight("CO3")
       C03
0.01666419
> 1/molweight("HCO3")
      HC<sub>0</sub>3
0.01638892
> 1/molweight(c("C2H5OH", "CO2", "H2O"))

6.2. Average elemental composition of biomass

The average elemental composition of marine plankton (Redfield ratio) is traditionally assumed to be $C_{106}H_{263}O_{110}N_{16}P_1$ (Redfield 1934; Redfield, Ketchum, and Richards 1963; Richards 1965), while Limnologists sometimes assume a ratio of $C_{106}H_{180}O_{45}N_{16}P_1$ (Stumm 1964). Since then, the ratio of C:N:P was widely agreed, but there is still discussion about the average of O and H. Anderson (1995) proposed a new formula $C_{106}H_{175}O_{42}N_{16}P_1$ for marine plankton and similarly Hedges, Baldock, Gélinas, Lee, Peterson, and Wakeham (2002), who used NMR analysis, found an elemental composition with much less hydrogen and oxygen ($C_{106}H_{175-180}O_{35-40}N_{15-20}S_{0.3-0.5}$) than in the original formula.

Function redfield can be used to simplify conversions between the main elements of biomass, where the default molar ratio can be displayed by:

The second argument of the function allows to rescale this to any of the constitutional elements, e.g. to nitrogen:

In addition, it is also possible to request the output in mass units, e.g. how many mass units of the elements are related to 2 mass units (e.g. mg) of phosphorus:

Finally, mass percentages can be obtained by:

or by using an alternative alternative elemental composition with:

> stumm <-
$$c(C = 106, H = 180, O = 45, N = 16, P = 1)$$

> $x <- redfield(1, "P", "mass", ratio = stumm)$
> $x / sum(x)$

Note however, that all these formulae are intended to approximate the **average** biomass composition and that large differences are natural for specific observations, depending on the involved species and their physiological state.

6.3. Pressure conversions

convert_p converts between the different barometric scales:

```
Pa bar at atm torr 1 101325.3 1.013253 1.033214 1 760.0008
```

6.4. Temperature conversions

Function convert_T converts between different temperature scales (Kelvin, Celsius, Fahrenheit):

6.5. Salinity and chlorinity

The relationship between Salinity, chlorinity and conductivity is in various functions:

- $> convert_StoCl(S = 35)$
- [1] 19.37394
- $> convert_RtoS(R = 1)$
- [1] 27.59808
- $> convert_StoR(S = 35)$
- [1] 1.236537

7. Finally

This vignette was made with Sweave (Leisch 2002).
